Measuring and Modelling Human Response to Foot-transmitted Vibration Exposure Katie Anne Goggins, 2019

Foot transmitted vibration (FTV) occurs when a worker is exposed to vibration through the feet and can occur when operating vibrating equipment such as bolters, jumbo drills or crushers or standing to operate mobile equipment such as locomotives and forklifts. Exposure to FTV has been linked to the development of vibration induced white feet, a vascular disorder with reduced circulation to the toes causing blanching. Vibration research has been focused on whole body vibration (WBV) and hand arm vibration with FTV being lumped in to standing WBV. This research includes but is not limited to resonant frequency identification, development of international standards governing safe exposure limits, personal protective equipment design and model development. It is the intention of this research to initiate research specifically for FTV. The first step to preventing harmful exposure is to identify the resonant frequencies at different anatomical locations on the foot.

Objective 1: The resonance of 24 anatomical locations on the foot was identified for 21 participants where the most notable differences in the average peak frequency occurred between the toes (range 99-147 Hz), midfoot (range 51-84 Hz) and ankle (range 16-39 Hz). As workers do not normally stand in a completely natural position, it was equally important to measure how altering the location of the centre of pressure (COP) changes resonance and the transmissibility of vibration through the foot.

Objective 2: The resonance at the same 24 anatomical locations was identified when the COP was pushed forward towards toes and backward towards heels. Generally, resonance at the measurement location increased when the COP was concentrated to a particular portion of the foot.

The third objective of this research was to reduce the measurements at 24 anatomical locations from the first two objectives down to a representative subset.

Objective 3: Multiple correspondence analysis was conducted on the peak transmissibility magnitude in order to assess structure displacement leading to increases in potential injury risk. Transmissibility results were analysed based on two magnitude thresholds at 2.0 indicating 100% amplification of the input signal and at 2.5 indicating 150% amplification. Results indicate that transmissibility measurements at the nail bed of first phalange, head of first metatarsal, head of second metatarsal and the lateral malleolus may be sufficient to effectively measure foot transmitted vibration when participants changed their COP location from natural forward and backward. Then a K-means analysis was conducted to minimize the anatomical locations necessary to capture the transmissibility response from 10 to 200 Hz and using the reduced locations a lumped parameter model was designed and validated.

Objective 4: Three locations, the nail of the big toe, the third metatarsal and the lateral malleolus were found to be sufficient for summarizing FTV transmissibility modulus. A three segment four degrees of freedom lumped parameter model of the foot-ankle system (FAS) was designed to model the transmissibility response at three locations when exposed to vertical vibration from 10 to 60 Hz. Reasonable results were found at the ankle, midfoot and toes in the natural standing position and forward COP. However, when the COP is backward, the model does not sufficiently capture the transmissibility response at the ankle. Determining the resonant frequencies of the FAS is important for the prevention of vibration induced injury. Resonance needs to be incorporated into the design of equipment tools, e.g. anti-vibration drills, isolated platforms and personal protective equipment, e.g. antivibration insoles or boots, can be modified to reduce vibration at the frequencies where tissue resonance occurs. These findings could also inform the development of new international standards for measuring, reducing exposure to FTV.

Whole-Body Vibration Therapy for Osteoporosis U. S. Department of Health and Human Services, Agency for Healthcare Research and Quality, 2013-04-06 Osteoporosis is a skeletal system disease characterized by low bone density and deterioration of bone tissue The clinical ranges for osteoporosis osteopenia and normal bone density are presented Osteoporosis affects 2 percent of men and 10 percent of women over the age of 50 in the United States In addition 49 percent of older women and 30 percent of older men in the United States have low bone density or osteopenia Osteoporosis is a significant public health problem that leads to increased bone fragility and greater fracture risk especially of the wrist hip and spine In an epidemiological study conducted in Switzerland 50 percent of all fractures in women and 24 percent in men were considered osteoporotic In the United States an estimated 1.5 million yearly osteoporotic fractures result in more than 500,000 hospitalizations 800,000 emergency room visits 2.6 million physician office visits and 180,000 nursing home placements Hip fractures in particular are associated with an increased risk of death Fractures can also cause pain height loss and functional disability as well as complications such as pressure sores and pneumonia By 2020 approximately half of all older Americans will be at risk for fractures from osteoporosis or osteopenia The U.S. Preventive Services Task Force recommends active screening for osteoporosis and early intervention to prevent bone fractures Current clinical guidelines recommend dietary and pharmacological interventions to treat osteoporosis and prevent bone fractures An increase of 1 standard deviation in bone mineral density in women would prevent 33 percent of hip fractures and 77 percent of vertebral fractures Despite proven effectiveness these treatments may have low rates of long term adherence Pharmacological interventions can result in adverse outcomes commonly minimal trauma atypical fractures esophageal irritation renal toxicity and osteonecrosis of the jaw Additionally requirements of pharmacological interventions may be burdensome for patients How vibration therapy increases bone density is not well understood One hypothesis suggests that vibration signals transmit and amplify into bone tissue directly activating mechanosensors in bone cells Animal studies have demonstrated that vibration increases the anabolic bone building activity of bone tissue and increases bone density Another hypothesis suggests that whole body vibration like other weight bearing exercise improves muscle strength and power by increasing neuromuscular activation Human studies on healthy volunteers examined adaptive muscle strength and performance after vibration therapy and found its effects to be similar to those of short term resistance exercise Several studies have shown whole body vibration therapy to improve muscle and bone circulation increasing the supply of nutrients needed to build bones This technical brief describes the state of the science and summarizes the key issues related to the use of whole body vibration therapy to improve bone density for the prevention and treatment of osteoporosis including modalities standards relevant patient populations outcomes measured and implications for future research This report's scope is confined to whole body vibration platforms designed and marketed for prevention and treatment of osteoporosis our review excludes exercise equipment with vibrating platforms intended for use in physical fitness or athletic regimens
