Dynamic Power Management

Dynamic Power Management Luca Benini,Giovanni DeMicheli,2012-12-06 Dynamic power management is a design methodology aiming at controlling performance and power levels of digital circuits and systems with the goal of extending the autonomous operation time of battery powered systems providing graceful performance degradation when supply energy is limited and adapting power dissipation to satisfy environmental constraints Dynamic Power Management Design Techniques and CAD Tools addresses design techniques and computer aided design solutions for power management Different approaches are presented and organized in an order related to their applicability to control units macro blocks digital circuits and electronic systems respectively All approaches are based on the principle of exploiting idleness of circuits systems or portions thereof They involve both the detection of idleness conditions and the freezing of power consuming activities in the idle components The book also describes some approaches to system level power management including Microsoft's OnNow architecture and the Advanced Configuration and Power Management standard proposed by Intel Microsoft and Toshiba These approaches migrate power management to the software layer running on hardware platforms thus providing a flexible and self configurable solution to adapting the power performance tradeoff to the needs of mobile and fixed computing and communication Dynamic Power Management Design Techniques and CAD Tools is of interest to researchers and developers of computer aided design tools for integrated circuits and systems as well as to system designers

DYNAMIC POWER MANAGEMENT ENERGY HARVESTING INTEGRATION Neetu Mehta,2023-05-30 Dynamic Power Management DPM is a technique employed in heterogeneous wireless sensor networks WSNs to optimize energy consumption by dynamically adjusting the power state of sensor nodes based on their current workload and requirements It involves selectively activating or deactivating components of the nodes to conserve energy while ensuring the desired network performance Energy Harvesting Integration refers to the incorporation of energy harvesting techniques into the WSN to supplement or replace the traditional battery based power supply Energy harvesting utilizes ambient energy sources such as solar wind vibration or thermal energy to generate electrical power for the sensor nodes This integration enables the nodes to replenish their energy levels and extend their operational lifetime without relying solely on finite battery power By combining Dynamic Power Management with Energy Harvesting Integration the heterogeneous WSN can intelligently adapt its power usage based on real time conditions and leverage harvested energy to mitigate the energy limitations This integration optimizes energy utilization prolongs the network's lifetime and enhances its resilience in environments with scarce energy resources

Online Learning Algorithms for Dynamic Power Management Zhen Ma,Rajesh Kumar Gupta,2006 Dynamic Power Management DPM is a major technique to reduce energy consumption for battery operated embedded systems Online DPM algorithms refer to strategies that switch the system to optimal power state according to the system idle period lengths at runtime In this paper we propose an online learning based power management technique which combines a low overhead stochastic learning automaton and threshold based DPM algorithms The simulation results show that the hybrid algorithm can achieve on an average of 5% and up to 20% energy savings than the online probability based approach while introduces on an average of 14% lower average latency than any other algorithm that has similar energy savings

Dynamic I/O Power Management for Hard Real-Time Systems ,2005 Power consumption is an important design parameter for embedded and portable systems Software controlled or dynamic power management DPM has recently emerged as an attractive alternative to inflexible hardware solutions DPM for hard real time systems has received relatively little attention In particular energy driven I/O device scheduling for real time systems has not been considered before We present the first online DPM algorithm which we call Low Energy Device Scheduler LEDES for hard real time systems LEDES takes as inputs a predetermined task schedule and a device usage list for each task and it generates a sequence of sleep working states for each device it guarantees that real time constraints are not violated and it also minimizes the energy consumed by the I/O devices used by the task set LEDES is energy optimal under the constraint that the start times of the tasks are fixed We present a case study to show that LEDES can reduce energy consumption by almost 50%

A Dynamic Power Management Schema for Multi-Tier Data Centers Aryan Azimzadeh,2016 An issue of great concern as it relates to global warming is power consumption and efficient use of computers especially in large data centers Data centers have an important role in IT infrastructures because of their huge power consumption This thesis explores the sleep state of data centers servers under specific conditions such as setup time and identifies optimal number of servers Moreover their potential to greatly increase energy efficiency in data centers We use a dynamic power management policy based on a mathematical model Our new methodology is based on the optimal number of servers required in each tier while increasing servers setup time after sleep mode to reduce the power consumption The Reactive approach is used to prove the validity of the results and energy efficiency by calculating the average power consumption of each server under specific sleep mode and setup time We introduce a new methodology that uses average power consumption to calculate the Normalized Performance Per Watt in order to evaluate the power efficiency Our results indicate that the proposed schema is beneficial for data centers with high setup time

Stochastic Learning Feedback Hybrid Automata for Dynamic Power Management in Embedded Systems, 2004 Dynamic Power Management DPM refers to the strategies employed at system level to reduce energy expenditure i.e. to prolong battery life in embedded systems. The trade off involved in DPM techniques is between the reductions of energy consumption and latency incurred by the jobs to be executed by the system. Such trade offs need to be decided at runtime making DPM an on line problem. In this context the contributions of this thesis are two fold. Firstly we formulate the DPM problem as a hybrid automaton control problem. We model a timed hybrid automaton to mathematically analyze various opportunities in optimizing energy in a given system model. Secondly stochastic control is added to the automata model whose control strategy is learnt dynamically using stochastic learning automata SLA. Several linear and non linear feedback algorithms are incorporated in the final Stochastic Learning Hybrid Automata SLHA model. Simulation based experiments show the expediency of the feedback systems in stationary environments. Further experiments are conducted using real trace data to compare stochastic learning strategies to the outcomes of several former predictive algorithms. These reveal that SLHA attains better trade offs than the other studied methods under certain trace data. Advanced characterization of trace sequences which allows a better performance of SLHA is a subject of further study.
